

THE ONE-PAGE RESULT TEST

QUESTION: can a reader be convinced by the figures alone?

Fig 1 Same policy + same scenario + same policy noise -> different outcomes.

Physics realization alone decides success.

Fig 2 Outcomes bifurcate (0.018 m vs 0.304 m; threshold 0.04 m), they do not jitter.

Sensitive scenarios show 2.7x the contact-timing variability (association only).

Fig 3 14.8% of single-realization views flip the SIGN vs an R=3 reference;

25.0% flip the practical category. Range across contrasts: 0%-56%.

Fig 4 Resolution floor: ~7.6-8.1 pp at R=1; ~4.4-4.7 pp at R=3.

Fig 5 Calibration predicts SIGN reliability (67%->97%) but NOT category (flat 72-78%).

VERDICT

The measurement contribution stands on frozen data alone:

a demonstrated failure mode, a quantified floor, a calibration that half-works.

The honest headline is a RESOLUTION LIMIT, not a claim about fast samplers.

WHAT THE FIGURES DO NOT SHOW

- No contrast is significant: 0 of 12 CIs exclude zero.
- No equivalence claim is licensed; absence of resolution is not evidence of parity.
- Slot/environment-index effects: NEED-E1.
- Causality of contact timing: MISSING-EVIDENCE.

CORRECTIONS APPLIED IN THIS PACKAGE

- Headline is 14.8%: strict sign REVERSALS. Supersedes 24% and 21.3%.
- 7 of 108 views are exact ties ($\Delta=0$); a tie is not a reversal.
- Same tie bug inflated the Fig 5 low bin: 44.4% -> corrected 66.7%.
- Pooled == unweighted (0.0 pp): weighting is not driving the number.
- The 5 pp band is a PREDECLARED PROJECT CONVENTION, not a community standard.
- The 108 views are 12 contrasts x 9 NESTED views, never 108 experiments.
